

On Cartan Geometries and the Formulation of a Gravitational Gauge Principle.

Gabriel Catren

SPHERE (UMR 7219) - Université Paris Diderot/CNRS

Cartan geometries \leftrightarrow *gravitation as a gauge theory?*

- **Gauge theories of gravity:** Utiyama (1956), Sciama, Kibble, Trautman, Hehl, Ne'eman, Isham, Macdowell & Mansouri, Stelle & West, etc.

- The theory of Cartan connections seems to provide the adequate geometric framework for accomplishing this task (c.f. Wise, Randonò).

- **Main bibliography:**

- **Mathematical:** E. Cartan, R.W. Sharpe, S. Kobayashi, P.W. Michor, and S. Sternberg.

- **Physical:** K.S. Stelle & P.C. West, *Spontaneously broken de Sitter symmetry and the gravitational holonomy group*, Phys. Rev. D, 21, 6, 1980.

- **General relativity:**

$$[g] = \frac{g}{\text{Diff}(M)} \rightsquigarrow \text{Unique metric \& torsionless connection (Levi-Civita connection)}$$

- **Yang-Mills theory:**

$$[\omega_G] = \frac{\omega_G}{\text{Aut}_V(P_G)}$$

where $P_G \rightarrow M$ is a G -principal bundle with G a Lie group and ω_G an Ehresmann conn.

Whereas a gauge field is represented by an Ehresmann connection on the internal spaces of a G -principal bundle over space-time,...

...the gravitational field is represented by a metric on the space-time itself.

Introduction

Gauging Gravity

Cartan's Program

Symmetry breaking

Cartan connection

Metric

Cartan Curvature

Development

Conclusion

- **“Metric” Einstein-Hilbert formulation:**

.metric g .

- **“Tetrad-connection” Palatini formulation:**

.Ehresmann conn. ω for the local Lorentz group (called *spin conn.*),

.tetrads, *vierbeine*, or moving frames $\theta \sim \sqrt{g}$.

- **Cartan formulation:**

. $\omega + \theta$ is a connection (!)... for the local Poincaré group?

... but not an Ehresmann conn., but rather a *Cartan connection*.

- The difference between **Y-M** theory & **GR** is reduced to the difference between Ehresmann and Cartan connections.

Cartan connection

Metric

Cartan Curvature

Development

Conclusion

- In the article

Sur les variétés à connexion affine et la théorie de la relativité généralisée (première partie),

(Annales scientifiques de l'E.N.S, 3^e série, tome 40, pp. 325-412, 1923)

... E. Cartan introduced the ***Cartan connections*** and proposed a generalization of **GR** to geom. with non-zero torsion.

- In the article

Les connexions infinitésimales dans un espace fibré différentiable

(Seminaire N. Bourbaki, 1948-1951, exp. n^o 24, pp. 153-168, 1950),

... C. Ehresmann formalized the notion of conn. by means of the theory of fiber bundles...

... and showed that Cartan conn. are a particular case of a more grl. notion, namely the notion of Ehresmann conn.

Cartan's conception was overshadowed by the notion of Ehresmann connection.

Motivations for “gauging” gravity

Introduction

Gauging Gravity

● Motivations for “gauging” gravity

- Gauge Principle in Yang-Mills Theory
- On Fiber Bundles
- On locality & interactions
- Different roles played by symmetry groups
- Towards a Gauge Principle for Gravity

Cartan's Program

Symmetry breaking

Cartan connection

Metric

Cartan Curvature

Development

Conclusion

● Pragmatic motivations:

.Since we know how to quantize **Y-M** theory, the reduction of the gap between **Y-M** and **GR** might be useful for quantizing gravity (c.f. **LQG**).

.It might be helpful for unifying gravity with the other **Y-M** interactions.

● Conceptual motivations:

♣ **Y-M** theory can be (partially) obtained from an astonishing heuristic argument, namely the ***gauge principle*** (**GP**):

Symmetry ↔ **Locality** ↔ **Interactions**

- Motivations for “gauging” gravity
- **Gauge Principle in Yang-Mills Theory**
- On Fiber Bundles
- On locality & interactions
- Different roles played by symmetry groups
- Towards a Gauge Principle for Gravity

$$\psi(x) \sim e^{i\alpha} \psi(x) \xrightarrow{\text{Ehresmann connection}} \psi(x) \sim e^{i\alpha(x)} \psi(x)$$

In order to construct a locally invariant theory it is necessary to introduce physical interactions in the form of Ehresmann connections.

- **“Kretschmann” objection:**

A mere epistemic requirement regarding the permissible coordinate transformations seems to imply non-trivial new physics.

- **Solution:**

Local gauge invariance is the epistemic consequence of the ontological commitment of the theory regarding the fund. geom. structure that it presupposes: ***fiber bundles***.

- Motivations for “gauging” gravity
- Gauge Principle in Yang-Mills Theory
- **On Fiber Bundles**
- On locality & interactions
- Different roles played by symmetry groups
- Towards a Gauge Principle for Gravity

- Common conception:

Fiber bundles = globally twisted generalizations of the Cartesian product of two spaces.

- However, even locally a G -principal bundle $P_G \xrightarrow{\pi} M$ is not a product space $U_i \times G$, with $U_i \subset M$...

... since $\pi^{-1}(x) \neq G$, but is rather a ***G -torsor*** or a ***principal homog. space***, ...

... i.e. a set on which G acts in a ***free*** and ***transitive*** manner.

- $\pi^{-1}(x)$ is isomorphic to G in a *non-canonical* way since it does not have a privileged origin.

- Each fiber can be identified with G only by fixing a local section $\sigma : U_i \rightarrow P_G$:

$$\begin{aligned} \psi : U_i \times G &\xrightarrow{\simeq} \pi^{-1}(U_i) && \text{(local trivialization of } P_G) \\ \psi(x, g) &\mapsto \sigma(x)g. \end{aligned}$$

Internal states in different fibers cannot be *intrinsically* compared.

On locality & interactions

Introduction

Gauging Gravity

Cartan's Program

Symmetry breaking

Cartan connection

Metric

Cartan Curvature

Development

Conclusion

- The requirement of local gauge invariance is just the “epistemic” counterpart of the fact...

... that internal states are not endowed with an intrinsic “*qualitative suchness*”.

- In Y-M theory, ***physical interactions*** in the form of Ehresmann conn. are necessary to overcome...

... (in a path-dependent or curved way)...

... the disconnection introduced by the spatio-temporal ***localization*** of matter fields.

A connection reconnects what space-time disconnects.

Introduction

- On Fiber Bundles
- On locality & interactions
- Different roles played by symmetry groups
- Towards a Gauge Principle for Gravity

Cartan's Program

Symmetry breaking

Cartan connection

Metric

Cartan Curvature

Development

Conclusion

- It is not the same to say...

... that the observables of the theory must be invariant under a symmetry group...

... than saying that the very degrees of freedom of the theory must be introduced in order to guarantee the invariance of the theory under a symmetry group.

- While the **Y-M** gauge fields are introduced in order to guarantee the invariance of the theory under $Aut_V(P_G)$...

... it is not clear to what extent the invariance under $Diff(M)$ plays such a “constructive” role in **RG**.

Cartan's Program

Symmetry breaking

Cartan connection

Metric

Cartan Curvature

Development

Conclusion

- Is it possible to reformulate GR as a theory that describes a dynamical conn. on a fibration over M ?

- And, what is the kind of locality guaranteed by such a gravitational connection?

- ***First evident answer:***

Spacetime is endowed with a ***natural bundle***, namely the ***tangent bundle*** TM ...

... and the Levi-Civita conn. is a law for \parallel -transporting vectors in TM .

- Generalized local models of vacuum
- Klein Geometries
- Locals models of gravitational vacuum
- Limitations of Klein's Erlangen Program
- Riemann + Klein = Cartan
- Summary (I)
- Summary (II)

- **Levi-Civita viewpoint:**

Tangent local model of vacuum (LMV) = Minkowski vector space.

- **Cartan viewpoint:** the Levi-Civita notion of connection has two flaws:

♠ Mink. **S-T** is a **homog. space**, i.e. there is a group

$$\Pi(3, 1) = \mathbb{R}^4 \rtimes SO^\uparrow(3, 1) \quad \text{Poincaré group}$$

that acts transitively on M .

.However, the Levi-Civita conn. only takes into account the rotational part $SO^\uparrow(3, 1)$ of $\Pi(3, 1)$,...

... neglecting in this way the symmetry associated to the fact that flat **S-T** does not have a privileged origin.

♣ If the topology of M is not that of Mink. **S-T**, i.e. if Mink. **S-T** is not the ground state of the theory...

... why should we use it Mink. **S-T** as a **LMV**?

Generalized local models of vacuum

Introduction

Gauging Gravity

Cartan's Program

● Cartan's criticism

● Generalized local models of vacuum

● Klein Geometries

● Locals models of gravitational vacuum

● Limitations of Klein's Erlangen Program

● Riemann + Klein = Cartan

● Summary (I)

● Summary (II)

Symmetry breaking

Cartan connection

Metric

Cartan Curvature

Development

Conclusion

- Cartan bypasses these two flaws by using more general **LMV**.

♠ Cartan starts with an *affine fiber bundle* (rather than a vector bundle)...

... in which the local structural group is the whole affine group of the **LMV**...

... incorporating the fact that the ground state lacks a privileged origin.

♣ Rather than using Mink. **S-T**, Cartan uses as **LMV** a homog. space adapted to the topology of **S-T**,...

...models that are given by the so-called *Klein geometries*.

- All in all

Tangent Minkowski vector space \rightsquigarrow *Tangent affine Klein geometry*.

- An **homog. space** (M, G) is a connected space M endowed with a **transitive action** of a Lie group G .

- Given $x_0 \in M$, the **surjective** map:

$$\begin{aligned} \pi_{x_0} : G &\rightarrow M \\ g &\mapsto g \cdot x_0. \end{aligned}$$

induces a bijection

$$G/H_0 \rightarrow M,$$

where $H_0 = \pi_{x_0}^{-1}(x_0) \subset G$ is the isotropy group of x_0 .

- Whereas H_0 leaves x_0 invariant, G/H_0 generates translations in M .
- The pair (G, H) with G/H a connected homog. space is called a **Klein geometry**.
- A **KG** (G, H) induces a canonical H -fibration $G \rightarrow G/H$, where G is called the **principal group** (“*Hauptgruppe*”) of the geometry.

- Cartan's criticism
- Generalized local models of vacuum
- Klein Geometries
- **Locals models of gravitational vacuum**
- Limitations of Klein's Erlangen Program
- Riemann + Klein = Cartan
- Summary (I)
- Summary (II)

- The relevant examples of **KG** (G, H) in the framework of gravitational theories are given by the vacuum solutions of the Einstein's equations with a cosmological constant Λ :

.Minkowski space-time ($\Lambda = 0$):

$$(\mathbb{R}^4 \rtimes SO^\uparrow(3, 1), SO^\uparrow(3, 1)),$$

.Anti-de Sitter space-time ($\Lambda < 0$):

$$(SO^\uparrow(3, 2), SO^\uparrow(3, 1)),$$

.de Sitter space-time ($\Lambda < 0$):

$$(SO^\uparrow(4, 1), SO^\uparrow(3, 1)).$$

- **Note:** in order to obtain a Klein geometry **KG** (G, H) from a homogeneous space, we have to choose an origin in the latter.

- Cartan's criticism
- Generalized local models of vacuum
- Klein Geometries
- Locals models of gravitational vacuum
- Limitations of Klein's Erlangen Program
- Riemann + Klein = Cartan
- Summary (I)
- Summary (II)

- Klein's marriage between **geometry** and **group theory** only works for homog. (i.e. symmetric) spaces:

“At first look, the notion of group seems alien to the geometry of Riemannian spaces, as they do not possess the homogeneity of any space with a principal group.”

E. Cartan, *La théorie des groupes et les recherches récentes de géométrie différentielle.*

- This limitation of Klein's Erlangen program can be bypassed by using the Klein symmetric spaces as local tangent models:

“In spite of this, even though a Riemannian space has no absolute homogeneity, it does, however, possess a kind of infinitesimal homogeneity; in the immediate neighborhood it can be assimilated to a Kleinian space.”

E. Cartan, *Ibid.*

- This generalization of Klein's program requires to go beyond the stance according to which the infin. models of a curved geom. must be given by Euclidean space.

- Cartan's criticism
- Generalized local models of vacuum
- Klein Geometries
- Locals models of gravitational vacuum
- Limitations of Klein's Erlangen Program

- Summary (I)
- Summary (II)

- **Riemannian Geometry** is locally modeled on **Euclidean Geometry** but globally deformed by curvature.
- **Klein Geometries** provide more general symmetric spaces than **Euclidean Geometry**.
- **Cartan's twofold generalization:**

Cartan Geometries are locally modeled on Klein Geometries but globally deformed by curvature

- In particular, a Riemannian geometry on M is a torsion-free Cartan geometry on M modeled on Euclidean space.

Summary (I)

Introduction

Gauging Gravity

Cartan's Program

- Cartan's criticism

Symmetry breaking

Cartan connection

Metric

Cartan Curvature

Development

Conclusion

- We shall start with a **Y-M** geometry (i.e., with a theory with purely *internal* affine symmetries):

$$\begin{array}{c}
 P_G \\
 | \\
 \omega_G \\
 \downarrow \\
 M
 \end{array}$$

where ω_G is an Ehresmann connection and G is the **Poincaré, de Sitter or anti-de Sitter affine group** that acts transitively on the vacuum solution of the theory.

- We shall then “*externalize*” some of the internal symmetries in order to induce geom. structures on M itself.

- We shall consider a **KG** (G, H) with $\dim(G/H) = \dim(M)$ where

$.G =$ **Poincaré, de Sitter or anti-de Sitter affine group.**

$.H =$ **Lorentz group.**

$.G/H =$ **group of translations** of the vacuum solution.

- Cartan's criticism
- Generalized local models of vacuum
- Klein Geometries
- Locals models of gravitational vacuum
- Limitations of Klein's Erlangen Program
- Riemann + Klein = Cartan
- Summary (I)
- Summary (II)

- Since G is now an affine group,...

... the fibers do not have a privileged point of attach. to M as it is the case for tg. *vector* bundles.

- In order to *attach* the fibers to M , i.e. to **solder** the internal geometry to the geometry of M ,...

... we have to “break” the Poincaré symmetry down to the Lorentz group H by selecting a point of attach. in each fiber.

- This amounts to reduce the Ehresmann-connected G -bundle P_G to a Cartan-connected H -bundle P_H :

- Associated bundle in homogeneous spaces
- Reduced H -bundle
- Reduction in a nutshell
- Attaching the **LMV** to M
- Symmetry breaking or partial gauge fixing?
- H -reductions as *partial* trivializations
- Canonical G -extension of an H -bundle

- An **Ehresmann conn.** on $P_G \rightarrow M$ is a **horizontal equivariant distribution** H defined by means of a G -eq. and \mathfrak{g} -valued 1-form ω_G on P_G such that

$$H_p = \text{Ker} (\omega_G)_p \subset T_p P_G.$$

- The conn. form ω_G satisfies:

$$.R_h^* \omega_G = Ad_{(h^{-1})} \omega_G, \text{ where } Ad \text{ is the adj. repr. of } G \text{ on } \mathfrak{g}.$$

$$.\omega_G(\xi^\#) = \xi \text{ ("vertical parallelism")} \text{ where}$$

$$\begin{aligned} \# : \mathfrak{g} &\rightarrow V_p P_G \\ \xi &\mapsto \xi^\#(f(p)) = \left. \frac{d}{d\lambda} (f(p \cdot \exp(\lambda\xi))) \right|_{\lambda=0}. \end{aligned}$$

Important: ω_G has values in the Lie algebra \mathfrak{g} of the structural group G .

● Canonical G -extension of an H -bundle

Cartan connection

Metric

Cartan Curvature

Development

Conclusion

- It might be possible to reduce (non-canonically) P_G to an H -bundle $P_H \rightarrow M$.

- To do so, we have to consider the associated G -bundle in homog. spaces

$$P_G \times_G G/H \rightarrow M.$$

- This bundle is obtained by attaching to each x a **LMV** $\simeq G/H$.

- It can be shown that

$$P_G \times_G G/H \cong P_G/H.$$

● Canonical G -extension of an H -bundle

Cartan connection

Metric

Cartan Curvature

Development

Conclusion

- The reduction of P_G to P_H can be defined either by a global section

$$\sigma : M \rightarrow P_G \times_G G/H \cong P_G/H$$

or, equivalently, by an equivariant function

$$\varphi : P_G \rightarrow G/H, \quad \varphi(pg) = g^{-1}\varphi(p).$$

- The reduced H -bundle $P_H \rightarrow M$ is given either by

$$P_H = \varphi_\sigma^{-1}([e])$$

or by the pullback of P_G along the section σ :

Reduction in a nutshell

- All in all, there is one-to-one correspondence between

Reduced H -subbundles P_H of P_G

Global sections $\sigma : M \rightarrow P_G/H$

or

Equivariant functions $\varphi : P_G \rightarrow G/H$

Cartan connection

Metric

Cartan Curvature

Development

Conclusion

- The reduction amounts to select a **point of attachment** $\sigma(x)$ in each $\mathbf{LMV} \simeq G/H$ at each x .

- By doing so, we shall identify

.each $\sigma(x)$ with x ,

.each $T_x M$ to the vertical tangent space to $\sigma(x)$.

- In this way, the **LMV** attached to x will be tangent to M at $\sigma(x)$.

- By selecting a point of att. for each x , we “break” the translational symm. of the **LMV**.

- $H = SO^\uparrow(3, 1)$ encodes the “unbroken” rotational symmetry.

Symmetry breaking or partial gauge fixing?

Introduction

Gauging Gravity

Cartan's Program

Symmetry breaking

- Ehresmann connections
- Associated bundle in homogeneous spaces
- Reduced H -bundle
- Reduction in a nutshell
- Attaching the \mathbf{LMV} to M
- Symmetry breaking or partial gauge fixing?
- H -reductions as *partial* trivializations
- Canonical G -extension of an H -bundle

Cartan connection

Metric

Cartan Curvature

Development

Conclusion

- Since the $\mathbf{LMV} \simeq G/H$ in which σ is valued are analogous to the manifold that parameterizes the \neq degenerated vacua in a theory with symmetry breaking....

... the field σ is sometimes called a **Goldstone field**...

... and the reduction process is understood as a symmetry breaking (c.f. Stelle & West).

- However, the reduction $P_H \hookrightarrow P_G$ defined by σ might also be understood as a...

... **gauge fixing of the G/H -translational local invariance**...

... **that is, as a *partial* gauge fixing of the G -invariance.**

H -reductions as *partial* trivializations

Introduction

Gauging Gravity

Cartan's Program

Symmetry breaking

● Ehresmann connections

● Associated bundle in homogeneous spaces

● Reduced H -bundle

● Reduction in a nutshell

● Attaching the **LMV** to M

● Symmetry breaking or partial gauge fixing?

● H -reductions as *partial* trivializations

● Canonical G -extension of an H -bundle

Cartan connection

Metric

Cartan Curvature

Development

Conclusion

- In particular, a reduction of P_G to a $\{id_G\}$ -principal bundle is given either by a section

$$s : M \rightarrow P_G \times_G (G / \{id_G\}) \cong P_G / \{id_G\} = P_G$$

or by a G -equivariant function

$$\varphi : P_G \rightarrow G / \{id_G\} = G,$$

where the reduced $\{id_G\}$ -bundle is

$$P_{\{id_G\}} = s^* P_G = \varphi^{-1}(id_G).$$

- Hence, a *complete reduction* with $H = \{id_G\}$ is a trivialization $s : M \rightarrow P_G$ of P_G .
- Instead of selecting a unique frame for each x as the trivialization s does...

... a H -reduction can be considered a sort of *partial trivialization* of P_G that selects a non-trivial H -set of frames for each x .

Canonical G -extension of an H -bundle

Introduction

Gauging Gravity

Cartan's Program

Symmetry breaking

- Ehresmann connections
- Associated bundle in homogeneous spaces
- Reduced H -bundle
- Reduction in a nutshell
- Attaching the **LMV** to M
- Symmetry breaking or partial gauge fixing?
- H -reductions as *partial* trivializations
- Canonical G -extension of an H -bundle

Cartan connection

Metric

Cartan Curvature

Development

Conclusion

- Whereas the reduction of the G -bundle P_G depends on the existence of a global section

$$\sigma : M \rightarrow P_G/H \cong P_G \times_G G/H$$

... a H -bundle $P_H \rightarrow M$ can be *canonically* extended to the associated G -bundle

$$P_H \times_H G \rightarrow M,$$

where the G -action is given by

$$[(p, g)] \cdot g' = [(p, gg')]$$

... and where the inclusion is given by

$$\begin{aligned} \iota : P_H &\hookrightarrow P_H \times_H G \\ p &\mapsto [(p, e)]. \end{aligned}$$

While the reduction of P_G to P_H is not canonical,
 P_H can always be extended to a G -bundle $P_H \times_H G$.

- Let's suppose that ω_G satisfies

$$\text{Ker}(\omega_G) \cap \iota_* TP_H = 0,$$

where $\iota : P_H \hookrightarrow P_G \dots$

... or, equivalently, that ω_G has no null vectors when restricted to P_H :

$$\text{Ker}(A \doteq \iota^*(\omega_G)) = 0.$$

- The 1-form $A : TP_H \rightarrow \mathfrak{g}$ defines a **Cartan connection** if

.for each $p \in P_H$, A induces a linear iso. $T_p P_H \cong \mathfrak{g}$ ("**absolute parallelism**")

.($R_h^* A$) $_p = Ad_{(h^{-1})} A_p$ for all $p \in P_H$ and $h \in H$.

.. $A(\xi^\sharp) = \xi$ for any $\xi \in \mathfrak{g}$ where $\sharp : \mathfrak{g} \rightarrow V_p P_G$.

- **The 1-form A cannot be an Ehresmann conn. on P_H since it is not valued in \mathfrak{h} .**

Reductive decomposition of \mathfrak{g}

Introduction

Gauging Gravity

Cartan's Program

Symmetry breaking

Cartan connection

● Induced Cartan connection on

P_H

● Reductive decomposition of \mathfrak{g}

● Coordinate & geometric soldering form

● Soldering the **LMV** to M

Metric

Cartan Curvature

Development

Conclusion

- Let's suppose that the **KG** (G, H) is **reductive**, i.e. that there exists a $Ad(H)$ -module decomposition

$$\mathfrak{g} = \mathfrak{h} \oplus \mathfrak{m}, \quad Ad(H) \cdot \mathfrak{m} \subset \mathfrak{m}$$

(in what follows $\mathfrak{m} \doteq \mathfrak{g}/\mathfrak{h}$).

- By composing with the projections, this decomp. of \mathfrak{g} induces a decomp. of A :

$$A = \omega_H + \theta,$$

where the so-called **spin connection**

$$\omega_H : TP_H \xrightarrow{A} \mathfrak{g} \xrightarrow{\pi_{\mathfrak{h}}} \mathfrak{h}$$

is an Ehresmann conn. on P_H and the so-called **soldering form**

$$\theta : TP_H \xrightarrow{A} \mathfrak{g} \xrightarrow{\pi_{\mathfrak{g}/\mathfrak{h}}} \mathfrak{g}/\mathfrak{h}$$

is a $\mathfrak{g}/\mathfrak{h}$ -valued 1-form on P_H that is

.horizontal: $\theta(\eta) = 0$ for vertical vectors $\eta \in VP_H$)

. H -eq.: $R_h^* \theta = h^{-1} \theta$

- Induced Cartan connection on P_H
- Reductive decomposition of \mathfrak{g}
- Coordinate & geometric soldering form
- Soldering the **LMV** to M

- While σ attaches the **LMV** to $x \in M$ at $\sigma(x)$, the $\mathfrak{g}/\mathfrak{h}$ -part θ of $A = \omega_H + \theta$ identifies each $T_x M$ to the vertical tg. space to the **LMV** at $\sigma(x)$.

- This is a consequence of $\text{Ker}(A) = 0$, since

$$A(v_h) = \omega_H(v_h) + \theta(v_h) = \theta(v_h) \neq 0 \in \mathfrak{g}/\mathfrak{h},$$

where v_h is a horizontal vector.

- Given the **coordinate soldering form**

$$\theta : TP_H \rightarrow \mathfrak{g}/\mathfrak{h},$$

the isomorphism

$$\Omega_{hor}^q(P_H, \mathfrak{g}/\mathfrak{h})^H \simeq \Omega^q(M, P_H \times_H \mathfrak{g}/\mathfrak{h}),$$

induces a **geometric soldering form**

$$\tilde{\theta} : TM \rightarrow P_H \times_H \mathfrak{g}/\mathfrak{h}$$

- The bundle $P_H \times_H \mathfrak{g}/\mathfrak{h}$ can be identified with the bundle of vertical tg. vectors to $P_G \times_G G/H$ along $\sigma : M \rightarrow P_G \times_G G/H$:

$$P_H \times_H \mathfrak{g}/\mathfrak{h} \simeq V_\sigma(P_G \times_G G/H).$$

- Induced Cartan connection on P_H
- Reductive decomposition of \mathfrak{g}
- Coordinate & geometric soldering form
- Soldering the LMV to M

- The *geometric soldering form*

$$\tilde{\theta} : TM \rightarrow P_H \times_H \mathfrak{g}/\mathfrak{h}$$

identifies each vector v in $T_x M$ with a geometric vector $\tilde{\theta}(v)$ in $P_H \times_H \mathfrak{g}/\mathfrak{h}, \dots$

... that is with a vertical vector tangent to $P_G \times_G G/H$ at $\sigma(x)$.

- The tg. space $T_x M$ is thus **soldered** to the tg. space to the homog. fiber $\simeq G/H$ of $P_G \times_G G/H$ at $\sigma(x)$.

The LMV are soldered to TM along the section σ .

- The *coordinate soldering form*

$$\theta_p : T_p P_H \rightarrow \mathfrak{g}/\mathfrak{h}$$

defines the $\mathfrak{g}/\mathfrak{h}$ -valued coordinates of $\tilde{\theta}(v)$ in the frame p .

● Soldering vs. canonical form

Cartan Curvature

Development

Conclusion

- The existence of a soldering form θ on P_H implies that P_H is isomorphic to a $GL(\mathfrak{g}/\mathfrak{h})$ -structure,...

... that is to a subbundle of the $GL(\mathfrak{g}/\mathfrak{h})$ -principal bundle LM of linear frames on M .

- Indeed, θ defines an application

$$\begin{aligned} f^\theta : P_H &\hookrightarrow LM \\ p &\mapsto f^\theta(p) : \mathfrak{g}/\mathfrak{h} \rightarrow T_{\pi(p)}M \end{aligned}$$

that identifies each element p in P_H with a frame $f^\theta(p) \in LM$ over $\pi(p) \in M$.

- Since $f^\theta : P_H \rightarrow LM$ is an H -morphism, $f^\theta(P_H)$ is a H -subbundle of LM .
- Such a reduction of LM amounts to define a Lorentzian metric on M .

- Reducing the frame bundle
- **Recovering the metric**
- Soldering vs. canonical form

- The metric g^θ on M can be explicitly defined in terms of the $Ad(H)$ -invariant scalar product $\langle \cdot, \cdot \rangle$ of $\mathfrak{g}/\mathfrak{h}$ by means of the expression

$$g^\theta(v, w) = \langle \tilde{\theta}_p(v), \tilde{\theta}_p(w) \rangle,$$

where $\tilde{\theta}_p(x) : T_x M \rightarrow \mathfrak{g}/\mathfrak{h}$.

- The H -invariance of $\langle \cdot, \cdot \rangle$ implies that $g^\theta(v, w)$ does not depend on the frame p over x .

The translational part θ of the Cartan connection A ...

... by inducing an isomorphism between P_H and a $SO(3, 1)$ -subbundle of LM ...

... induces a Lorentzian metric g^θ on M .

Soldering vs. canonical form

Introduction

Gauging Gravity

Cartan's Program

Symmetry breaking

Cartan connection

Metric

● Reducing the frame bundle

● Recovering the metric

● Soldering vs. canonical form

Cartan Curvature

Development

Conclusion

- The soldering form $\theta \in \Omega^1(P_H, \mathfrak{g}/\mathfrak{h})$ is the pullback by f^θ of the **canonical form**

$$\theta_c : T(LM) \rightarrow \mathfrak{g}/\mathfrak{h}$$

on LM given by:

$$\begin{aligned} \theta_c : T_{e(x)}(LM) &\rightarrow \mathfrak{g}/\mathfrak{h} \\ \tilde{v} &\mapsto e(x)^{-1}(\pi_*(\tilde{v})). \end{aligned}$$

where

$$e(x) : \mathfrak{g}/\mathfrak{h} \rightarrow T_x M$$

is a frame on $T_x M$.

- Contrary to the canonical form θ_c on LM , the soldering form θ on P_H is not canonical...
... since it comes from the restriction of the arbitrary Ehresmann conn. ω_G on P_G to P_H .
- This is consistent with the fact that θ defines a degree of freedom of the theory.

Curvature of the Cartan connection

Cartan Curvature

● Curvature of the Cartan connection

● On Cartan flatness

● (Maurer-)Cartan flat connection

Development

Conclusion

- The **Cartan curvature** $F \in \Omega^2(P_H, \mathfrak{g})$ of a Cartan geom. (P_H, A) is given by

$$F = dA + \frac{1}{2}[A, A] = F_{\mathfrak{h}} + F_{\mathfrak{g}/\mathfrak{h}}.$$

- The **curvature** $R \in \Omega^2(P_H, \mathfrak{h})$ of a Cartan geom. (P_H, A) is given by

$$R \doteq d\omega_H + \frac{1}{2}[\omega_H, \omega_H] = F_{\mathfrak{h}} - \frac{1}{2}[\theta, \theta]_{\mathfrak{h}}.$$

- The **torsion** $T \in \Omega^2(P_H, \mathfrak{g}/\mathfrak{h})$ of a Cartan geom. (P_H, A) is given by

$$T \doteq d\theta + \frac{1}{2}([\omega_H, \theta] + [\theta, \omega_H]) = F_{\mathfrak{g}/\mathfrak{h}} - \frac{1}{2}[\theta, \theta]_{\mathfrak{g}/\mathfrak{h}}.$$

- In general., **Cartan flatness** does not imply $R = 0$ and $T = 0$:

$$F = 0 \Leftrightarrow \begin{cases} R = -\frac{1}{2}[\theta, \theta]_{\mathfrak{h}} \\ T = -\frac{1}{2}[\theta, \theta]_{\mathfrak{g}/\mathfrak{h}} \end{cases}$$

- The standard for Cartan flatness $F = 0$ is given by the “curved” **LMV** $\simeq (G, H)$.
- The so-called **symmetric models** satisfy

$$[\mathfrak{g}/\mathfrak{h}, \mathfrak{g}/\mathfrak{h}] \subseteq \mathfrak{h},$$

which implies

$$T = F_{\mathfrak{g}/\mathfrak{h}} \rightsquigarrow F = (R + \frac{1}{2}[\theta, \theta]_{\mathfrak{h}}) + T.$$

- T naturally appears as the “translational” component of F .

● On Cartan flatness

● (Maurer-)Cartan flat connection

Development

Conclusion

- Let's consider the canonical H -fibration $G \rightarrow G/H$ of the **KG** (G, H) .
- The **Maurer-Cartan form** A_G of G is given by

$$\begin{aligned} A_G(g) : T_g G &\rightarrow \mathfrak{g} \\ \xi &\mapsto (L_{g^{-1}})_* \xi, \end{aligned}$$

where $L_{g^{-1}} : G \rightarrow G$ is the left translation defined by $L_{g^{-1}}(a) = g^{-1}a$ and it satisfies

$$\begin{aligned} R_g^* A_G &= Ad(g) A_G \\ dA_G + \frac{1}{2} [A_G, A_G] &= 0 \end{aligned}$$

Maurer-Cartan form = Flat Cartan connection on $G \rightarrow G/H$.

H -parallel transports

Introduction

Gauging Gravity

Cartan's Program

Symmetry breaking

Cartan connection

Metric

Cartan Curvature

Development

● H -parallel transports

● Development

● Infinitesimal developments

Conclusion

- ω_H defines parallel transports in the associated bundle

$$P_H \times_H \mathfrak{g}/\mathfrak{h} \simeq V_\sigma(P_G \times_G G/H),$$

that is parallel transports of vectors tg. to the **LMV** along the section

$$\sigma : M \rightarrow P_G \times_G G/H.$$

- Since the geom. soldering form $\tilde{\theta}$ defines an identification

$$TM \xrightarrow{\cong} P_H \times_H \mathfrak{g}/\mathfrak{h},$$

the Ehresmann conn. ω_H transports vectors tg. to M .

- The ω_H -parallel transports coincide with the levi-Civita parallel transports.
- Now, $A = \omega_H + \theta$ does not only \parallel -transport “internal” states (tg. vectors in this case) as in **Y-M** theory (by means of ω_H)...

... but also the spatiotemporal locations themselves (by means of θ).

- Let $\gamma : [0, 1] \rightarrow M$ be a curve on M and $\tilde{\gamma} : [0, 1] \rightarrow P_H$ any lift of γ .
- Since $P_H \subset P_G$, the curve $\tilde{\gamma}$ is in P_G .
- If we use ω_G for \parallel -transporting $\tilde{\gamma}(t)$ to $\pi^{-1}(x_0)$ along γ for all $t \in [0, 1]$, we obtain a curve $\hat{\gamma}$ in $\pi^{-1}(x_0)$.

- By using the projection

$$P_G \xrightarrow{\varrho} P_G/H \simeq P_G \times_G G/H,$$

we can define a curve $\gamma^* = \varrho(\hat{\gamma})$ in the fiber of $P_G \times_G G/H$ over x_0 called the **development of γ over x_0** .

- In this way, any curve $\gamma : [0, 1] \rightarrow M$ can be “*printed*” on the **LMV** over x_0 .
- It can be shown that:
 - . γ^* only depends on γ and is independent from the choice of $\tilde{\gamma}$.
 - . The devel. of a closed curve might fail to close by an amount given by T .

The torsion measures the non-commutativity of the translational parallel transports.

- Since the development is obtained by projecting a \parallel -transport defined by ω_G onto $G/H, \dots$

... the only relevant part of ω_G is the $\mathfrak{g}/\mathfrak{h}$ -valued part, namely θ .

- Given an infin. displacement $v \in T_x M$, the **geometric soldering form**

$$\tilde{\theta} : TM \rightarrow P_H \times_H \mathfrak{g}/\mathfrak{h} \simeq V_\sigma(P_G \times_G G/H)$$

defines an infin. displacement in the LMV on x_0 at the point of attachment $\sigma(x)$.

- This means that the point of attachment at $x + v$ will be developed in the fiber above x into the point $\sigma(x) + \tilde{\theta}(v)$.
- In other terms, the translational part θ of A defines the γ -dependent image of any $x \in M$ in the **LMV** at x_0 .

Translational locality: this identification is dynamically defined by the translational component of the Cartan gauge field A .

Cartan connection

Metric

Cartan Curvature

Development

Conclusion

● Conclusion (I)

● Conclusions (II)

● Further Research...

● The End

- The theory of Cartan geometries allows us to put together ω_H and θ into a unique Cartan connection

$$A \left\{ \begin{array}{l} \omega_H \text{ Gauges the local Lorentz symmetry} \\ \theta \left\{ \begin{array}{l} \text{Gauges the local translational symmetry} \\ \text{Induces a metric } g^\theta \text{ on } M \end{array} \right. \end{array} \right.$$

... that gauges the **local affine gauge invariance** defined by the affine group G that acts transitively on the vacuum solution of the theory.

- This can be done by reducing a **Y-M** geometry

$$(P_G \rightarrow M, \omega_G)$$

by means of a partial gauge fixing

$$\sigma : M \rightarrow P_G \times_G G/H$$

that breaks the translational invariance of the **LMV** $\simeq G/H$.

Conclusions (II)

Introduction

Cartan's Program

Symmetry breaking

Cartan connection

Metric

Cartan Curvature

Development

Conclusion

● Conclusion (I)

● Conclusions (II)

● Further Research...

● The End

- In GR (where $T = 0$), the consideration of a local *affine* symmetry instead of the smaller local Lorentz symmetry has no effects.

- If we relax the condition $T = 0$, then ω_H and θ are indep. geom. structures and the gravitational field must be described by the whole $A = \omega_H + \theta$.

- Since the **LMV** is not necessarily Minkowski **S-T**, the affine group G is not necessarily the Poincaré group.

Further Research...

Cartan connection

Metric

Cartan Curvature

Development

Conclusion

● Conclusion (I)

● Conclusions (II)

● Further Research...

● The End

- Clarify the relationship between the **local translational invariance** gauged by θ and the **invariance under diffeomorphisms** of M ...

... being these symmetries related by the soldering

$$\tilde{\theta} : M \rightarrow V_{\sigma}(P_G \times_G G/H)$$

which identifies the external infinitesimal translations in M with the internal translations in the internal **LMV**.

- Clarify the nature of the reduction process: **dynamical symmetry breaking** or **partial gauge fixing**?

- Analyze the different actions S that can be constructed from the Cartan connection A .

The End

Thanks for your attention !!!
